```
unsigned int atomicDec(unsigned int* address,
                       unsigned int val);
```

reads the 32-bit word **old** located at the address **address** in global or shared memory, computes **(((old == 0) | (old > val)) ? val : (old-1))**, and stores the result back to memory at the same address. These three operations are performed in one atomic transaction. The function returns **old**.
